

The goal my program aims to meet is the development of a survey that quizzes users on their ability to survive zombie apocalypses.

The program is executed, and variables storing the question list, scores, and user answers are generated (1).  
Once this is accomplished, an introduction explaining the purpose of the program is provided to the user (2).  
Following this the program grabs a piece of code that pushes forth a question present within the list addressed prior (3).  
This question is then displayed in the console (4).  
Then user are given the opportunity to answer the question correctly. If this is done successfully, a point is added under the score variable. If done so incorrectly, no points are added onto the score variable (5).  
At the completion of this, the program is asked whether the end of the list has been reached. If false, the user is commanded back to obtaining the next question in the list. If this is true, the program is ended. (6)
